Class 0-III

- ▶ In terms of observability of dust composition, outside the solar system, limited to IR and MM.
- ▶ will lead to observational biases

extract from Bam Acke thesis 2005, see ref. cited

Ebel, 2000, JGR 105, 10365.

Physical effect : evolution of the flow rates

Molster et al. 2002, Posch et al. 2002, Cami 2002 ...

- Correlation between wind density and condensates
 - Low loss mass : Simple oxides (quenching)
 - High loss mass : Amorphous silicates like ISM ones
 - Even higher : Crystalline silicates

Silicates "astromineralogy"

Olivines ($Mg_{2x}Fe_{2-2x}SiO_4$)	Formula	Name
	Mg_2SiO_4	Forsterite
	Fe_2SiO_4	Fayalite
Pyroxenes ($Mg_xFe_{1-x}SiO_3$)	Formula	Name
	$Mg_2Si_2O_6$	Enstatite
	$Fe_2Si_2O_6$	Ferrosilite
		(hypersthene)
	$CaMgSi_2O_6$	Diopside
	$CaFeSi_2O_6$	Hedenbergite

Disks models : the simplest flat passive case

e.g. Lynden-Bell & Pringle 1974; Adams, Lada, Shu 1988

- ▶ Power absorbed by $dS \approx \frac{\sigma T_*^4 R_*^2}{r^2} \sin(\alpha) dS$
- ▶ $\approx \frac{\sigma T_*^4 R_*^2}{r^2} dS \frac{R_*}{r}$
- ▶ Power radiated by $dS \approx \sigma T^4(r) dS$
- ▶ $T(r) \approx T_* \left(\frac{r}{R_*}\right)^{-3/4}$

Flat disk SED

Passive disks : flared disk

e.g. Kenyon & Hartmann 1987

- ▶ Expected due to hydrostatic equilibrium that gas/dust scale height and therefore α increase with radius.
- ▶ $\alpha_{flared} > \alpha_{flat}$, intercept more stellar flux
- ▶ $T(r) \propto r^{-2/5}$

Flared disk radiative equilibrium

Chiang & Goldreich 1997

- ▶ Stellar light absorbed in the upper layer where $\tau_V \approx 1$
- ▶ $T(\text{surface}) > T(\text{blackbody})$ (flaring + $\kappa(\nu)V \gg \kappa(\nu)IR$)
- ▶ IR emitted by surface outward detected ($\tau_{IR} \ll \tau_V$)
- ▶ IR emitted inward absorbed if $\tau_{IR} \approx 1$ (still related to α !!!).

An geometry change near the dust sublimation ?

Dullemond, Dominik & Natta 2001

- ▶ Interface cavity/dust sublimation zone.
- ▶ Puffed-up and hotter rim (directly exposed to stellar flux).
- ▶ Will affect the shadowed region just behind (Mid-ir suppression).

SED need for this inner disk wall

Natta et al. 2001

- ▶ Some SED show infrared deficit "Clearing" (DM Tau, GM Aur, Calvet et al. 2005)
- ▶ SED evidence of gaps in the first 10's AU ?

Interferometry in the IR

Disk IR luminosity scales with size e.g. Monnier et al. 2005

NIR Excess observed at all disk angles

Not a wall !

Isela & Natta 2005

- ▶ smoother inner puffed-up rim.
- ▶ Less sensitive to disk orientation as observed.

Insights ?

- ▶ No correlation between 850 or 1300 μm excess and PAHs features
- ▶ Not correlated with the disk mass but the surface ?
- ▶ No correlation between relative PAHs features strength and UV
- ▶ 3.3/6.6 μm flux ratio varies from 9% to 94%
- ▶ and is apparently independent of stellar UV field
- ▶ Sources with faintest 60 μm means faintest PAHs
- ▶ No correlation disk mass with PAHs emission \Rightarrow surface layers excitation ?

Acke & van den Ancker 2004

Spitzer's spectra of T Tauri

LkH α 330, C2D program, Geers et al. 2005, Protostars and Planets V

- ▶ Confirmed detection of PAHs in about 15% of observed sources.
- ▶ ... but may be up to 45%
- ▶ Difficulty to observe the 7.7 and 8.6 μm features, blended with silicates.

Spitzer's spectra of Herbig Ae/Be

Sloan et al. 2005

- ▶ 6.2 μm and 7.7 μm shifted to higher wavelengths
- ▶ 2 out of 4 sources display aliphatic emission
- ▶ Variation in the 7.9 μm /11.3 μm ratio : ionisation state ?

Modele de PAHs dans les disques

Habart et al. 2004

- ▶ Model "standard" idem au modele ISM
- ▶ $N_c = 100$, $T_{\text{eff}} = 10500\text{K}$, $L = 32L_{\odot}$, $M_{*} = 2.4M_{\odot}$, $M_{\text{disk}} = 0.1M_{\odot}$, $R_{\text{in}} = 0.3\text{AU}$, $R_{\text{ext}} = 300\text{AU}$, Flared

Modele de PAHs dans les disques

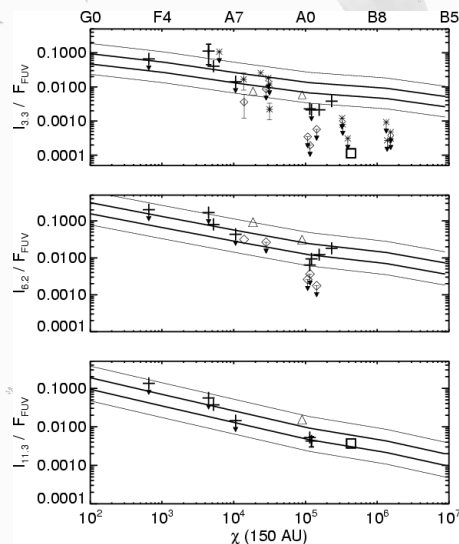

- ▶ Other parameters :
- ▶ ionized PAHs (lower CH modes)
- ▶ dehydrogenated PAHs (lower CH modes, enhance CC modes)

Habart et al. 2004

Comparison with some obs

Habart et al. 2004

- ▶ Objects with strong UV have weak $3.3\mu\text{m}$!
- ▶ The authors propose PAHs are destroyed or disk dissipated.
- ▶ integrated spectra are not good (need spatial resolution)
- ▶ compatible with large neutral or small ionized
- ▶ If present, provide an additional source of opacity and chemical reactant, should expect differences wrt silicates disks

Modele de PAHs dans les disques

- ▶ Other parameters :
- ▶ lower sizes ($N_c=40$ instead of $N_c=100$)

Habart et al. 2004

Spitzer's spectra of T Tauri

- ▶ Ground based obs start to resolve the PAH emission.
- ▶ Emission originate at (up to ?) 100-150 AU
- ▶ Geers et al. 2004; van Boekel et al. 2004; Habart et al. 2004
- ▶ If coming from 1AU would produce much higher fluxes
- ▶ Line flux for T Tauri 1-2 orders of magnitude higher than expected disk + ZAMS models (without taking into account UV from accretion shocks)
- ▶ Inner disk PAH abundance lower because destroyed (multi-photon process)

Size modification

Coagulation
MAC with size
Distributions
gas phase accretion
coagulation
sedimentation

Implications ?

- ▶ Silicates in the ISM are almost 100% “amorphous”
- ▶ (<0.4% [Kemper et al. 2004](#))
- ▶ and in the Rayleigh limit (small)
- ▶ all sources display at least 30% of big grains
- ▶ In disks observed, there is removal of small grains (otherwise we would see them !)
- ▶ grains are bigger than ISM (sensitivity bias, maybe even bigger)

Surface reactions

Size modification

Coagulation
MAC with size
Distributions
gas phase accretion
coagulation
sedimentation

Implications ?

- ▶ crystal/amorph. $\approx 35\%$
- ▶ higher stellar mass \rightarrow more crystal
- ▶ sources with crystal. sil. have more large grains
- ▶ Forsterite (Mg_2SiO_4) / Enstatite (MgSiO_3)
Low crystallinities/ High crystallinities
- ▶ All sources with more than $2.5M_{\odot}$ have a high fraction of big grains.

Van Boekel et al. 2005 and ref therein

Astrophysical timescales

- ▶ low energy ions dose is about $10 \text{ ions cm}^{-2} \cdot \text{s}^{-1}$ during a few 10^8 years [Jones et al. 1996](#)
- ▶ Grains receive therefore the equivalent of $10^{25-26} \text{ eV} \cdot \text{cm}^{-1}$ from SN ejecta
- ▶ Can fully amorphize 40 Angström grains, can explain ISM amorphous feature.

Irradiation doses, [Brucato et al. 2004](#), [Jager et al 2003](#)

Implication: radial mixing in disks !

- ▶ Crystalline silicates ($T_{\text{form}} \approx 1000\text{K}$) mixed with ices ($T_{\text{subl}} \approx 100\text{K}$)
- ▶ Radial mixing, reprocessing, X ray

The existence of some surface reactions

Much before class II, Field stars probe the onset and distribution of ices

Murakawa et al. 2000

- ▶ $\tau_{\text{H}_2\text{O}} (\nu_1, \nu_3) = \alpha(A_v - A_{\text{th}})$
- ▶ Abundance $10^{-4} - 10^{-5} N_{\text{H}} \neq \text{Gas}$ phase timescales
- ▶ surface reactions involving atomic oxygen needed
- ▶ well known for the formation of H_2 that surfaces required

UV photons versus cosmic rays

Adapted from Gerakines et al. 2001

- ▶ **UV photons**
 - ▶ Photochemistry (break specific bonds)
 - ▶ Penetration depth mixture dependant
 - ▶ Stopped by a few molecular layers
 - ▶ Ionise species
- ▶ **Cosmic Rays**
 - ▶ Break bonds
 - ▶ Penetration depth depends on stopping power
 - ▶ Goes through the grain
 - ▶ Ionise and generate secondary electrons

Grain surfaces indirect influence

- ▶ Ices : inhibitors/promoters for gas phase chemistry.
- ▶ Coupling of gas and dust chemistry (need for grains to reform H_2 efficiently at the surface layer)

Observed with line ice mantles profiles ?

Dartois 2006

- ▶ influence on a weighted size distribution may be present.

Mass absorption change with size

For an absorbing material:

e.g. Miyake & Nakagawa 1993, Kruegel & Siebenmorgen 1994

- ▶ ... but still size above about 50nm (otherwise nanoparticles effects and then molecular)
- ▶ low size parameter ($2\pi a/\lambda \ll 1$) $\kappa \propto$ volume
- ▶ intermediate size parameter ($2\pi a/\lambda \approx 1$) κ highest (best coupling of wave vector to grain size)
- ▶ low size parameter ($2\pi a/\lambda \gg 1$) $\kappa \propto$ surface

A jump into disks in the mm : spectral index β

- ▶ Flux received from a disk in the mm:
- ▶ Optically thin:

$$F(\nu) \propto \kappa(\nu) [\text{cm}^2 \cdot \text{g}^{-1}] B_\nu(T_{\text{dust}}) M_{\text{dust}} / d^2$$
- ▶ Rayleigh-Jeans limit:

$$F(\nu) \propto \nu^2 \kappa(\nu) [\text{cm}^2 \cdot \text{g}^{-1}] T_{\text{dust}} M_{\text{dust}} / d^2$$
- ▶ Outside the solid material strong absorption bands
 If $\kappa(\nu) \propto \nu^\beta$ then $F(\nu) \propto \nu^{\beta+2}$
 The β of dust can be inferred from the observed flux slope minus 2.

$\beta \approx 1$ in the mm for circumstellar disks, Why ?

- ▶ Large fluffy grain ?
- ▶ Grain with sizes of the order of the wavelength ?
- ▶ Chemical composition ?
- ▶ Optical thickness effect ?
- ▶ Temperature effects ?

mm dust index change in disks wrt ISM

Beckwith & Sargent 1991

Consequences:

- ▶ Some grain properties have changed.
- ▶ With β , Mass determination and slope changes.
- ▶ The Dynamical masses requires this change in mass abs coeff (e.g. Hogerheijde et al. 2003; ref in talk by A.D., S.G.), otherwise unstable disks

Optical thickness

- ▶ If the disk is not fully optically thin at mm wavelengths
- ▶ $\beta \approx (1 + \Delta)(\alpha - 2)$
- ▶ with Δ ratio of thick to thin (Beckwith & Sargent 1991)
- ▶ it makes β higher

Composition

- ▶ Various components tested by e.g. (Pollack et al. 1994)
- ▶ authors say silicates and organics are dominant sources of grain opacities
- ▶ H₂O ice (also present in spherical cores and beta almost the same)
- ▶ Low κ and n at long wavelength, a moderate effect if pure
- ▶ but may be important if allow to stick together high n, κ material (H₂O matrix effect).

Shape and Fluffiness ?

- ▶ κ ten times higher in the geom. regime.
- ▶ κ same in the Rayleigh regime (volume)
- ▶ κ smoother in the intermediate regime
- ▶ Increases the size parameter and coupling of the grains.
- ▶ Make an antenna if one dim. large for the same volume.

Compact

FIG. 4. Mass opacities (in cgs units) of single-sized compact dust particles ($f = 1$) for various radii a (0.01 μm to 100 m) composed of the intimate mixture of silicate and H₂O-ice, where the abundances of dust particles with respect to the H₂ gas are assumed to be solar. Curves for $a \leq 10 \mu\text{m}$ are almost identical at $\nu \approx 10^{12.5}$ Hz.

Fluffy

FIG. 8. Mass opacities of porous single-sized dust particles. The filling factor of dust materials f is taken to be 0.1. Except for the porosity of dust particles, the same as Fig. 4. Curves for $a \leq 10 \mu\text{m}$ are almost identical at $\nu \approx 10^{12.5}$ Hz.

sedimentation

Size increase by gas phase accretion

- ▶ $\rho_{\text{gas}} / \rho_{\text{dust}} \approx 100$
- ▶ but only a few 10^{-3} to 10^{-2} in mass is accretable (i.e. not in H, H₂, He ...)
- ▶ increase almost independent of initial grain size (i.e. each grain acquire the same small thickness)
- ▶ small (tiny) increase of large size
- ▶ ... large increase of small sizes

Composition and evolution of grains

Distributions

gas phase accretion

coagulation

sedimentation

Size increase by gas phase accretion

- ▶ moderate influence on lowering UV extinction.
- ▶ cannot account for mm emissivities.

Some effects of coagulation

Hily-Blant

et al. 2006

- ▶ Increase of the upper size cut-off @ fixed mass

Size distribution modification : coagulation

- ▶ large disappearance of the small grains.
- ▶ strong influence on UV properties.
- ▶ possibility to grow to mm sizes without cosmic abundance limit.
- ▶ Counterbalancing mechanism ?
- ▶ If grains in disks have grown bigger than $\sim 1\text{cm}$, one need for a change in size distribution slope @ large grain radius, otherwise inconsistent

Some effects of coagulation on gas chemistry

Hily-Blant et al. 2006, see also ref therein

- ▶ Coupled to a PDR code Le Boulot et al. 1993

Some effects of coagulation

Hily-Blant et al. 2006

- ▶ $^{12}\text{CO}/^{13}\text{CO}/\text{initial}(^{12}\text{C}/^{13}\text{C})$ @ 100,400,800 AU
- ▶ Affects also vertically the $^{12}\text{CO}/^{13}\text{CO}$ ratio

Some effects of coagulation

Hily-Blant et al. 2006

- ▶ Increasing a_+ affects more than increasing UV flux.
- ▶ The CO photodissociation occurs deeper in the disk.

Some effects of coagulation

Hily-Blant et al. 2006

- ▶ then the integrated $^{12}\text{CO}/^{13}\text{CO}$ ratio

- ▶ Phase separation
- ▶ Affects largest grains in a distribution
- ▶ Therefore affect much less the transfer in the UV !
